1. Source data

→ May be just tables (not even RDB)

We should have Endurant tables → Each record must be an endurant instance → these tables include id, type, optional att, and event observation.

but is it?

* multiple endurants can exist in one table.

We may also have event table(s) if we are lucky

↳ each row is an event observation.

↳ The table(s) must give us type, time → The identity is going to be defined somehow.

E20 can be in any table (event or endurant)

we may need to make data discrete.

2. Identify CIC (concrete individuals candidate)

- First set of candidates come from the tables.
- Second set comes from domain
- 3rd set comes from → Avas medical example
  - ↳ student vs prof example

Classification approaches may come handy or ODBA mapping.

where put normalization? Is source still the source after normalization?

3. Resolution → Semantic (two discrete obsv pointing to the same CIC)

→ structural (coming from inaccuracy of how data is structed)

- No object resolution (bc has been done already)

- Relator resolution may be needed. Relation edge vs Relator

- Event resolution → needs a definition for event identity
